ABSTRACT

The International North Pacific Fisheries Commission began a research program in 1955 to determine the ocean distribution and migrations of Pacific Salmon. The Pacific Salmon Investigations program of the Northwest and Alaska Fisheries Center, National Marine Fisheries Service-, NOAA, conducted one phase of these investigations, making 1601 drift gillnet sets from 1955 to 1972 in the North Pacific Ocean--from the western Aleutian Islands eastward in the Gulf of Alaska and in the Bering Sea.

This report describes cephalopods (almost entirely squids) that were taken in addition to salmon during these studies. Approximately 25% of all gillnet sets yielded cephalopods; catch per set ranged from 1 to 178 squids. Date, location, water temperature, and mesh size of sets that produced squids are given. Those squids that were identified are listed, and a brief description of their range and maximum size is given.

Six species of squid and one species of octopod were taken in the gillnets; Onychoteuthis borealijaponicus, Gonatopsis borealis, Gonatus spp.,

Berryteuthis spp., Ommastrephes bartramii, Chiroteuthis spp., and Japetella heathi. The most frequently caught squid, Onychoteuthis borealijaponicus, may be sufficiently abundant in late summer and fall north-of the subarctic boundary to warrant investigation as a potential commercial species.

Ommastrephes bartramii which may be abundant south of the subarctic boundary also warrants investigation. Other species were not taken in sufficient quantity by gillnetting to indicate commercial potentialities although some of the gonatids could contribute to a commercial catch depending to some extent on the type of fishing gear used.

INTRODUCTION

The International North Pacific Fisheries Commission (INPFC) began a research program in 1955 to determine the ocean distribution and migrations of Pacific salmon and the continent of origin of salmon taken on the high seas. A major part of this program has involved high-seas sampling by member nations using surface gillnets, purse seines, and longlines. The history and objectives of INPFC research are summarized by Jackson (1963) and Manzer et al. (1965).

The Pacific Salmon Investigations program of the Northwest and Alaska Fisheries Center (NWAFC) conducted one phase of the INPFC investigations. They fished surface gillnets to study the distribution, migrations, and environmental relationships of salmon. Cephalopods (almost entirely squids) were taken incidentally in these operations and although only a small percentage were preserved and later identified, the numbers were sufficient to provide some information on the distribution of squids in the area surveyed. Of 1,601 drift gillnet sets made by this program, 398 sets yielded between 1 and 178 cephalopods. This report describes the species of squid taken, their distribution, size composition, and commercial potentialities.

METHODS AND MATERIALS

Fishing procedures are described in Manzer et al. (1965) and in INPFC Annual Reports for 1955 to 1972. (Anonymous 1956-1960; Hanavan 1961; French 1962, 1964a, 1964b, 1966; French et al. 1967a, 1967b, 1969, 1970, 1971, 1972, 1973, 1974). Surface gillnets were fished for about 13 h at each station mostly during hours of darkness. The nets averaged 26 shackles (91.4 m per shackle) long and were 4 fathoms (7.3 m) deep. Mesh sizes were normally 2.50 in (64 mm), 3.25 in (83 mm), 4.50 in (114 mm), and 5.25 in (133 mm), from 1955 through 1960. In some years, other mesh sizes were added to the gillnet string. Normally, 4 shackles each of 2.50, 3.25, and 5.25 in mesh and 12 shackles of 4.50 in mesh were used. In 1955, a 2.25 in (.57 mm) mesh and in some later years 51 mm and 99 mm mesh were used. The depth of gillnets was also increased from 4 to 12 fm (21.9 m) in some years (1965-67). Most squids were taken in the 2.50 (64 nun) to 3.25 in (83 mm) mesh.

From 1955 to 1967 multifilament nylon gillnets were used, but beginning in 1962 monofilament gillnets were added to the strings. In this report, we make no distinction between the two types of nets. It is possible that one type may fish better than the other; however, our data are insufficient to make that determination.

In the early years of the program, few squids were saved as storage facilities on vessels were limited; however, records were kept of the numbers of squid taken by mesh size from each set. Detailed information by cruise and set number, date, location, and surface water temperature of those sets containing squids are presented in Table 1. Locations of all sets which produced squid are presented in Figure 1. Those squid that were saved for later examination were measured and identified to species. Locations of capture for identified specimens are presented

Table 1. Pacific Salmon Investigations gillnet sets with cephalopods.

Column headings defined:

CRU = Cruise number

HRS = Hours the gear was fished

TEMP C° = Surface temperature

CPUE = Catch per unit effort (#Squid/Shackle .hour)

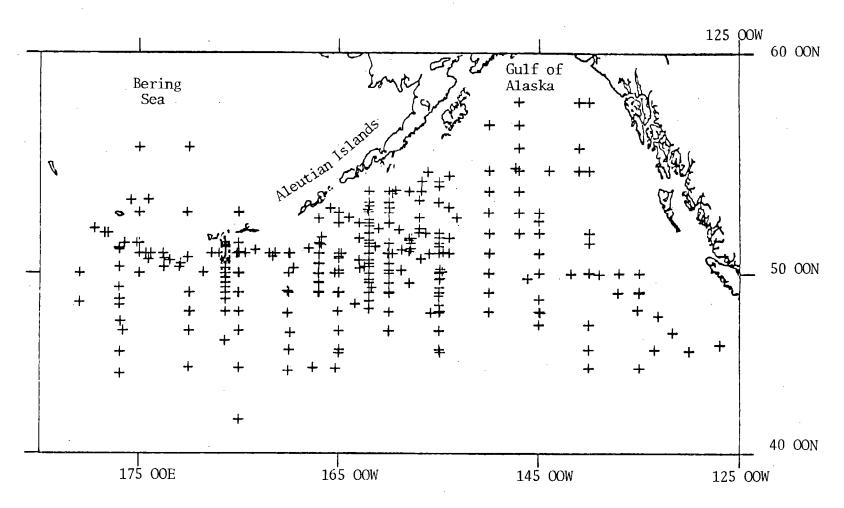

Figure 1. Gillnet sets which yielded squids, 1955-72.

in Figure 2; data on their capture, location, and mesh size in which they were caught are presented in Table 2.

Squid specimens returned from the field were preserved in 10% Formalin, in 1957 and frozen fresh in all other years. They were identified, measured, weighed, and in most instances sexed by the senior author. The laboratory procedure was to allow the frozen specimens to thaw and drain overnight. Excess moisture was wiped from individuals and the dorsal mantle length (DML) was measured in millimeters using calipers and a meter stick. Individual specimens were then weighed on a platform scale having 5 g graduations and sexed. The presence or absence of spermatophores in Needham's sac in the male was noted and the length of the nidamental gland in females was recorded as an indication of maturity.

RESULTS

Cephalopods representing five families (four squids, one octopod) were caught in gillnets in the North Pacific Ocean during salmon investigations. Information on these cephalopods, their size, distribution, and potential for a fishery are presented in the following sections.

Onychoteuthis borealijaponicus

The only member of this genus found in the North Pacific Ocean, it ranges from Baja California, Mexico north in the eastern North Pacific Ocean to the Gulf of Alaska and in the western North Pacific Ocean, from off Japan north to the Kurile Islands. Although records are scant, it presumably ranges across the North Pacific Ocean along the subarctic boundary and seasonally (summer and fall) at higher latitudes into subarctic waters. (Young 1972, Bernard 1980, Murata et al 1976, Naito et al 1977a, and the present paper).

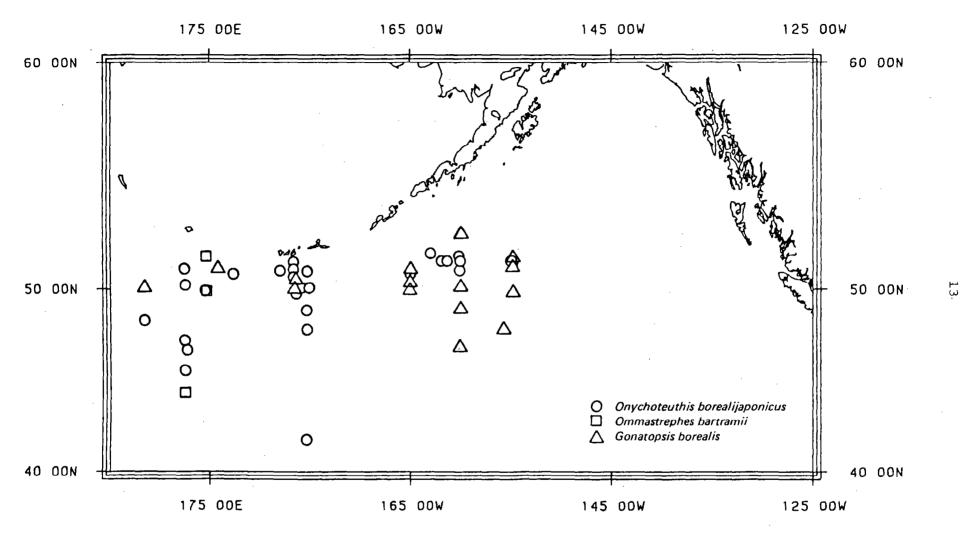

Figure 2. Locations where identified squids were captured, 1955-72.

^{0.} bor. - Onychoteuthls borealiJaponicus

J. hea. - Japatella heathi

Records of this genus from the tropical Pacific and Hawaiian waters are most certainly 0. banksii (Young 1972).

According to Naito et al. (1977a), O. borealijaponicus inhabits the northern portion of the subtropical zone and the southern portion of the subarctic zone 1/. They found that O. borealijaponicus was present in surface waters that fell between 1° and 20° C. but was mostabundant where the temperature was from 6° to 14° C. Squids identified during this study, mostly O. borealijaponicus (which constituted 94% of the total squid examined), were caught in surface waters of 6.9° to 12.8° C, which agrees with the findings of Naito et al. (1977a). Most were caught where surface water temperatures ranged from 9° to 13° C (Figure 3).

Based on these data, it is reasonable to conclude that O. borealijaponicus may be present from August through October in North Pacific waters where these temperatures occur. Test fishing in these waters could determine if this species is sufficiently abundant to support a commercial jig fishery.

Of the female reproductive organs, the paired nidamental glands are the most readily accessible, and they increase in size as maturity approaches. The lengths of these glands were measured from 74 females taken 23-24 August 1971 (Cruise 53) in an attempt to judge maturity in females. Of these glands, 75% fell within the length range of 40 to 54 mm (Figure 4a). The relationship between the length of nidamental glands and dorsal mantle length is presented in Figure 4b. We draw no conclusions from these data but suggest that until additional information becomes

^{1/} See Dodimead et al. (1963) and Favorite et al. (1976) who describe the subarctic boundary and the oceanography of the subarctic Pacific region.

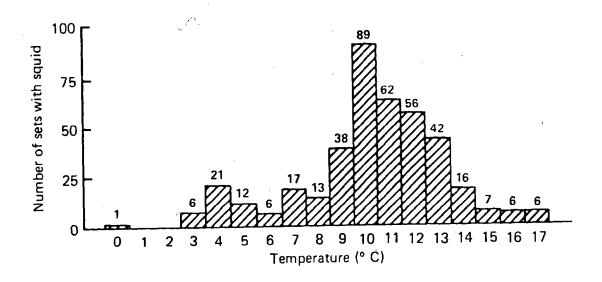

Figure 3. Gillnet sets in which squids were taken, by surface water temperature.

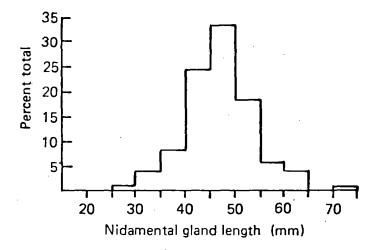

Figure 4a. Nidamental gland length from 74 female <u>Onychoteuthis</u> borealijaponicus captured 23-24 August 1971.

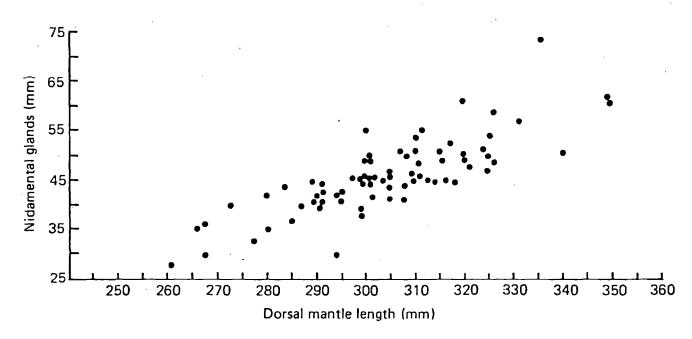

Figure 4b. Relationship between Nidamental gland length and Dorsal mantle length of 74 female <u>Onychoteuthis borealijaponicus</u> captured 23-24 August 1971.

available, females of this species with nidamental gland length of 40 mm and larger and dorsal mantle lengths of over 29 cm are approaching maturity. It is also possible that there may be considerable difference in the dorsal mantle length of mature females.

In males, the presence of spermatophores in Needham's sac was regarded as evidence of approaching maturity. The presence or absence of spermatophores was noted for males taken during cruises 53 (August 1971) and 54 (August 1972). The lengths and weights of specimens with and without spermatophores in Needham's sac were quite different (Table 3).

| collection | males | length (mm) | weight (g) | length (mm) | weight (g) |
| Cruise 53 23-24 August | | (N= | =29) | (N= | 11) |
| 1971 | 40 | 260.7 | 362.6 | 234.4 | 265.9 |
| Cruise 54 | | (N= | =13) | (N: | =19) |
| 4-22 August 1972 | 32 | 256.0 | 355.8 | 235.8 | 273.2 |

Reproductive data indicated that many of the males and females in the catch were approaching sexual maturity as the season progressed. Although gillnets may have been selective for large squids, it is likely that maturing squids of this species congregated in the subarctic waters of the North Pacific Ocean south of the Alaska Peninsula and the Aleutian Islands in the late summer and fall preparatory to spawning.

Additionally, during Cruise 54, sets 16 and 17 (August 4-5) contained 12 males and only 1 female; sets 18 and 19 (August 11-12) contained 14 males

and 7 females; sets 25-26-27 (August 18-19-20) contained 10 males and 62 females. The decrease of numbers of males relative to females during late August agrees with findings by Naito et al. (1977a). Naito et al. (1977a) suggested that the lower abundance of males in catches during August may be related to spawning activity. Murata et al. (1976) suggested that in the western Pacific O. borealijaponicus spawns on southward migration in late fall or winter.

Of the O. <u>borealijaponicus</u> examined, most were taken during Cruise 53 in August 1977 from south of Amchitka, Aleutian Islands (464 caught) and during Cruise 54 in August 1972 from south of Chirikof Island to the eastern Aleutian Islands (127 caught). The number of O. <u>borealijaponicus</u> measured, weighed, and sexed from Cruises 53 and 54 were 247 and 122, respectively.

Length-weight relationships for males and females are shown in figures 5 and 6. Data on lengths and weights of 0. borealijaponicus that were tabulated are summarized below:

| Area and sex of squid | Leng | Weight | (g) | |
|-----------------------|---------|--------|----------|------|
| | Range | mean | Range | mean |
| South of Amchitka Is. | | | | |
| Males | 212-269 | 257 | 200-525 | 343 |
| Females | 243-352 | 306 | 325-990 | 640 |
| South of Chirikof I. | | | | |
| Males | 207-282 | 244 | 180-475 | 304 |
| Females | 251-361 | 307 | 330-1100 | 655 |

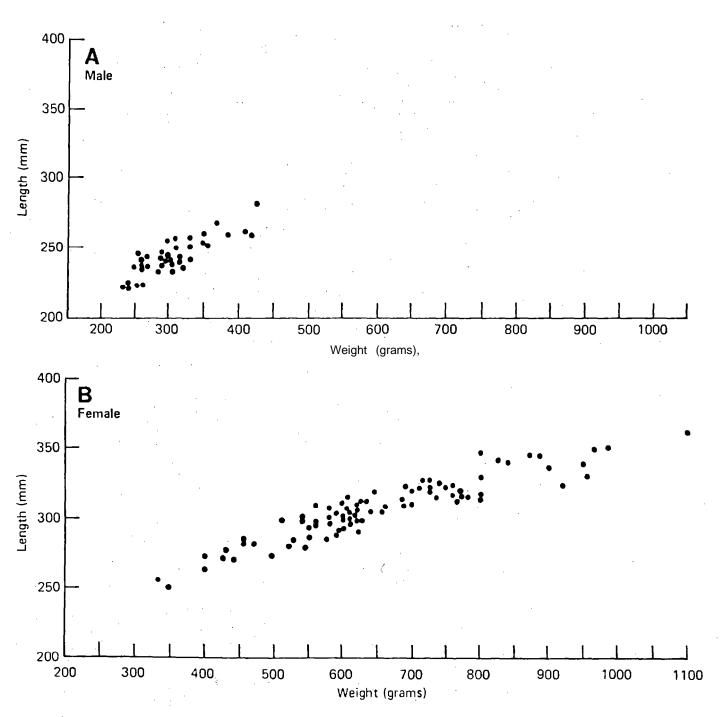

Figure 5. Length-weight relationships of male and female Onychoteuthis borealijaponicus taken during August 1972, south of the Alaska Peninsula and the eastern Aleutian Islands.

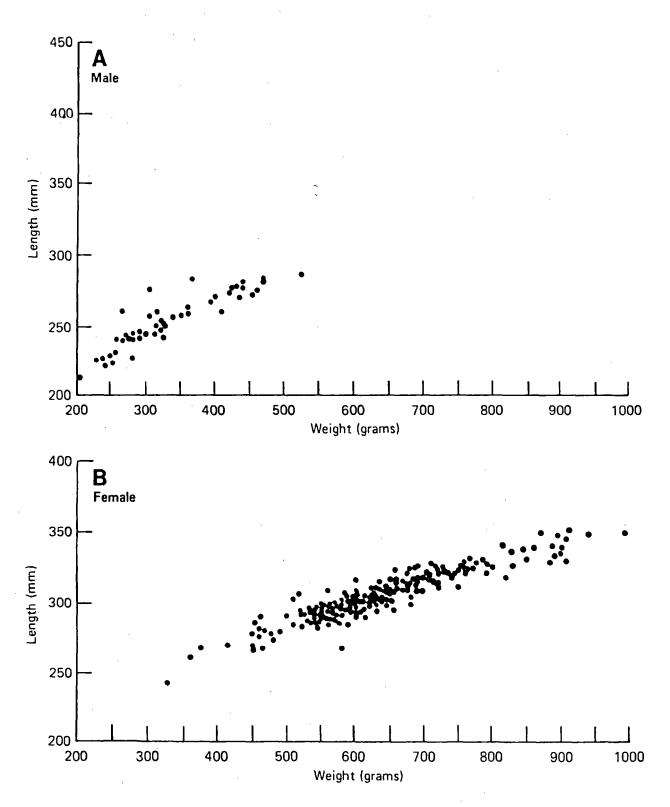

Figure 6. Length-weight relationships of male and female Onychoteuthis borealijaponicus taken during August 1971. south of Amchitka Island and the western Aleutian Islands.

These data agree with those of Naito et al. (1977b) who report a maximum mantle length in males of 30 cm (ours was 28.2 cm) and in females of 37 cm (ours was 36.1 cm). It is important to point out here that since most Onychoteuthis were caught in the smaller mesh sizes, it is possible the nets were selective for only large Onychoteuthis and that the length frequencies obtained here may not be representative of all Onychoteuthis present in the area.

Length-weight relationships between 0. borealijaponicus taken in August 1971 south of the western Aleutians and in August 1972 from south of the eastern Aleutians and eastward to south of Chirikof Island, exhibit similar growth patterns. We may postulate that this species matures in late summer and early fall at about the same rate across the North Pacific, based on the condition of reproductive glands and size.

O. <u>borealijaponicus</u> may be sufficiently abundant in Alaskan surface waters north of the subarctic boundary in summer and fall, where they reach mean lengths (DML) of 26.5 cm (males) 30.7 cm (females) and mean weights of 32 kg (males) .65 kg (females), to support a commercial jig fishery. Methods used to jig this species along with catch per unit of effort data in the northwestern Pacific are discussed by kurata et al. (19761, Murata and Ishii (1977) and Okutani (1977). Results of experimental jigging for this species in the northeastern Pacific are discussed by Bernard (19801.

Gonatopsis borealis

This species ranges from Baja California, Mexico (Young 1972), north into subarctic waters and west to the coast of Japan. Naito et al. (1977a) stated that G. borealis inhabits only the subarctic zone.

5. <u>borealis</u> was taken in gillnets during all seasons of the year:

January, February, March, May, July, August, and October. This species
was the only squid taken in January and February of 1970 and 1971 when

surface water temperatures registered 3.4° to 4.4° C. Naito et al. (1977b) lists maximum mantle lengths of 27 cm (males) and 29 cm (females); however, Okutani and Satake (1978) identified two specimens from the stomachs of sperm whales that measured 32 and 48 cm DML. Our largest specimen measured 24.8 cm (not sexed). Of those that were sexed, the largest male measured 20.3 cm, and the largest female was 16.2 cm.

Gonatus spp.

Members of this genus range from Baja California, Mexico, north around the Pacific rim to Japan and into subarctic waters of the North Pacific Ocean and the Bering Sea. Young (1972), Bublitz (1981), Kubodera and Okutani (1981), and Jefferts (1981) have described from seven to nine species in this genus from the eastern North Pacific Ocean and Bering Sea.

Gonatus (six specimens) in our collection have not been identified to species. Catches by date were 15 July 1966, DML 291 mm; 7 August 1968, 87 mm; 8 June 1970, 295 mm; August 1971, 1 male 330 mm, and 2 females with DML of 265 and 329 mm and weights of 200 and 375 g. Some of these specimens may be referable to Gonatus madokai (Kubodera and Okutani 1977, Bublitz 1981). Surface water temperatures in which Gonatus spp were taken ranged from 6.4° to 8.5° C.

Berryteuthis spp

This genus ranges across the North Pacific Ocean from California to

Japan and into the Bering Sea in subarctic waters. Two species have been

described: B. magister and B. anonychus.

The only B. <u>magister</u> in our collection was taken in August 1971; it was a male measuring 152 mm DML and weighing 250 g. B. <u>magister</u> shifts to benthic waters as it reaches sexual maturity (Naito et al. 1977).

While some members of the family Gonatidae may be taken in surface waters, it will be more productive to fish mature <u>Berryteuthis</u> near the bottom along the edge of the continental shelf and slope with trawl gear.

Ommastrephes bartramii

According to Naito et al. (1977a), this species is primarily an inhabitant of subtropical surface waters in the western North Pacific east to about 180° longitude. Murata et al. (1976) also reported that this species occurs primarily in the warmer surface waters. Bernard (1981) described an experimental fishery for this species off the west coast of Vancouver Island in the eastern North Pacific in 1980, and mentions that it is found across the warm and temperate waters of the North Pacific.

We have identified 11 O. <u>bartramii</u> from the gillnet catches. Of the 11, 7 were taken in July from about 50° to 53°N, and 175°E in surface water temperatures of 9.8° to 9.9°C, and four were taken in October 1965 in. 44°40'N, 173°02'E in surface water temperatures of 12°C. O. <u>bartramii</u> taken in 1957 were measured but not sexed; they measured 375, 380, 385, 387, 415, and 420 mm DML. Naito et al. (1977b) list maximum DML of 48 cm (females) and 41 cm (males).

The potential for a fishery on 0. bartramii along the subarctic boundary in summer and fall certainly warrants investigation. Bernard (1980) stated that large squids of this species tend to tear off of the jigs. Gillnets are usually used to capture this species and could be restricted to waters south of the subarctic boundary where salmonids do not occur.

Chiroteuthis spp.

One <u>Chiroteuthis</u> spp. was caught in a surface gillnet on 27 March 1968 in 49°46'N, 176°29'W. The surface water temperature was 3.6°C. Only the head and arms were recovered; tentacles and body were apparently lost when the net was hauled.

Japetella <u>heathi</u>

One small octopus, J. heathi, was taken by surface gillnet the night of 23-24 August 1971 in 50°50'N, 177°19'E. The surface water temperature was 10°C.

Summary

The squid 0. <u>borealijaponicus</u> was taken incidentally in surface gillnets set for salmonids along the subarctic boundary and northward in sufficient numbers to indicate a possible potential for a jig fishery in the north Pacific from the Gulf of Alaska westward to the Aleutian Islands in summer and fall.

0. <u>bartramii</u> was also taken from the subarctic boundary and southward and is probably present in sufficient numbers to support a fishery. Most <u>Gonatopsis borealis</u> were taken in winter; however, some were taken in summer and fall and this species may be taken in an <u>Q</u>. <u>borealijaponicus</u> fishery. Other species taken in surface gillnets were <u>Gonatus</u> spp., <u>Berryteuthis</u> spp., <u>Chiroteuthis</u> spp. and <u>Japetella heathi</u> and while these species are present in the fishery area, it is doubtful- if they would contribute significantly to 'the catch. <u>Berryteuthis magister</u>, which usually settle to benthic waters as they mature, are taken incidentally in the north Pacific and Bering Sea trawl fisheries and would probably not be taken by a jig fishery.

ACKNOWLEDGEMENTS

The authors thank Richard G. Bakkala and Robert R. French, NWAFC,
Seattle, Washington, and Clyde F. E. Roper, Department of Invertebrates,
U. S. National Museum, Washington D. C., for their critical review of the
manuscript. The authors also wish to thank Janet Holbrook and Violet Arajo,
NWAFC, for their assistance in typing the several drafts of this manuscript.
